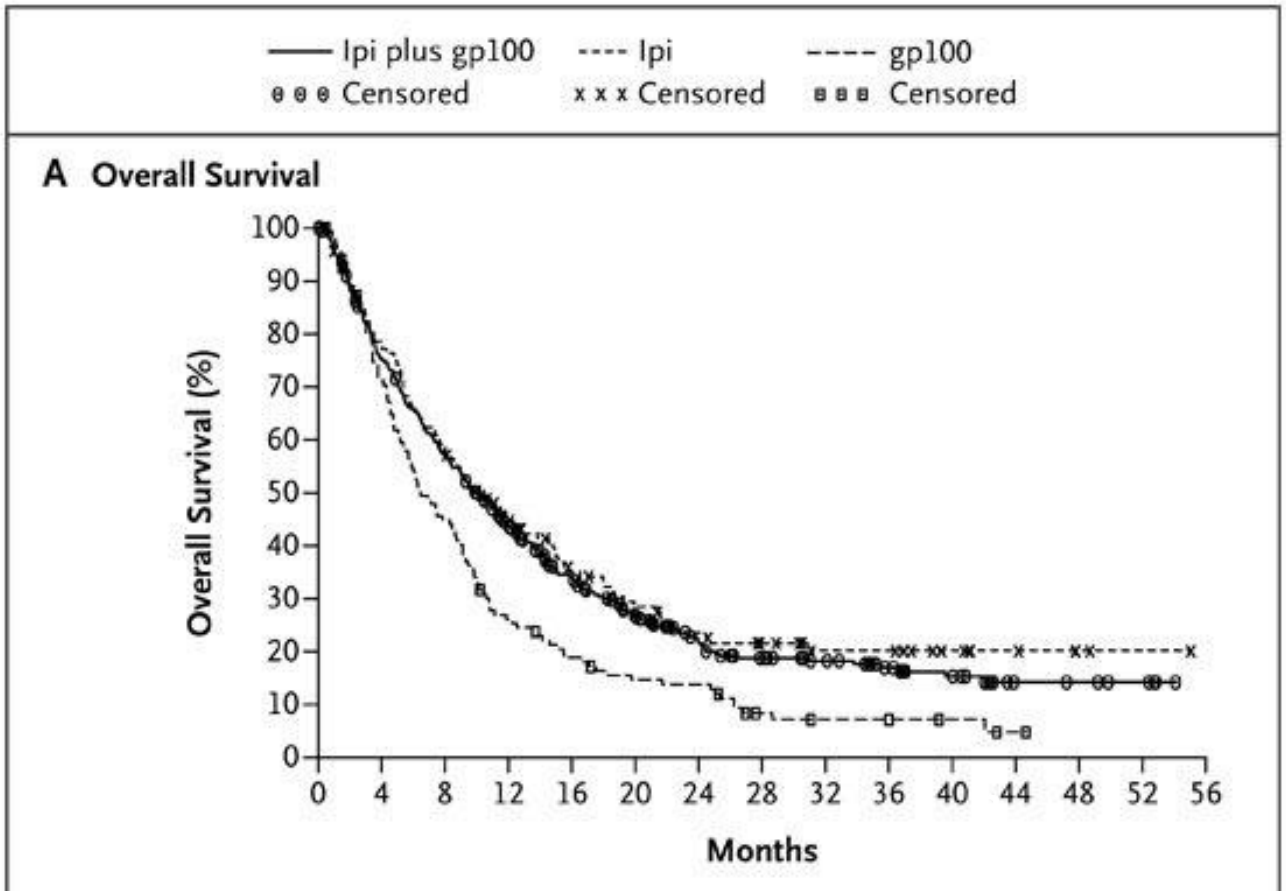
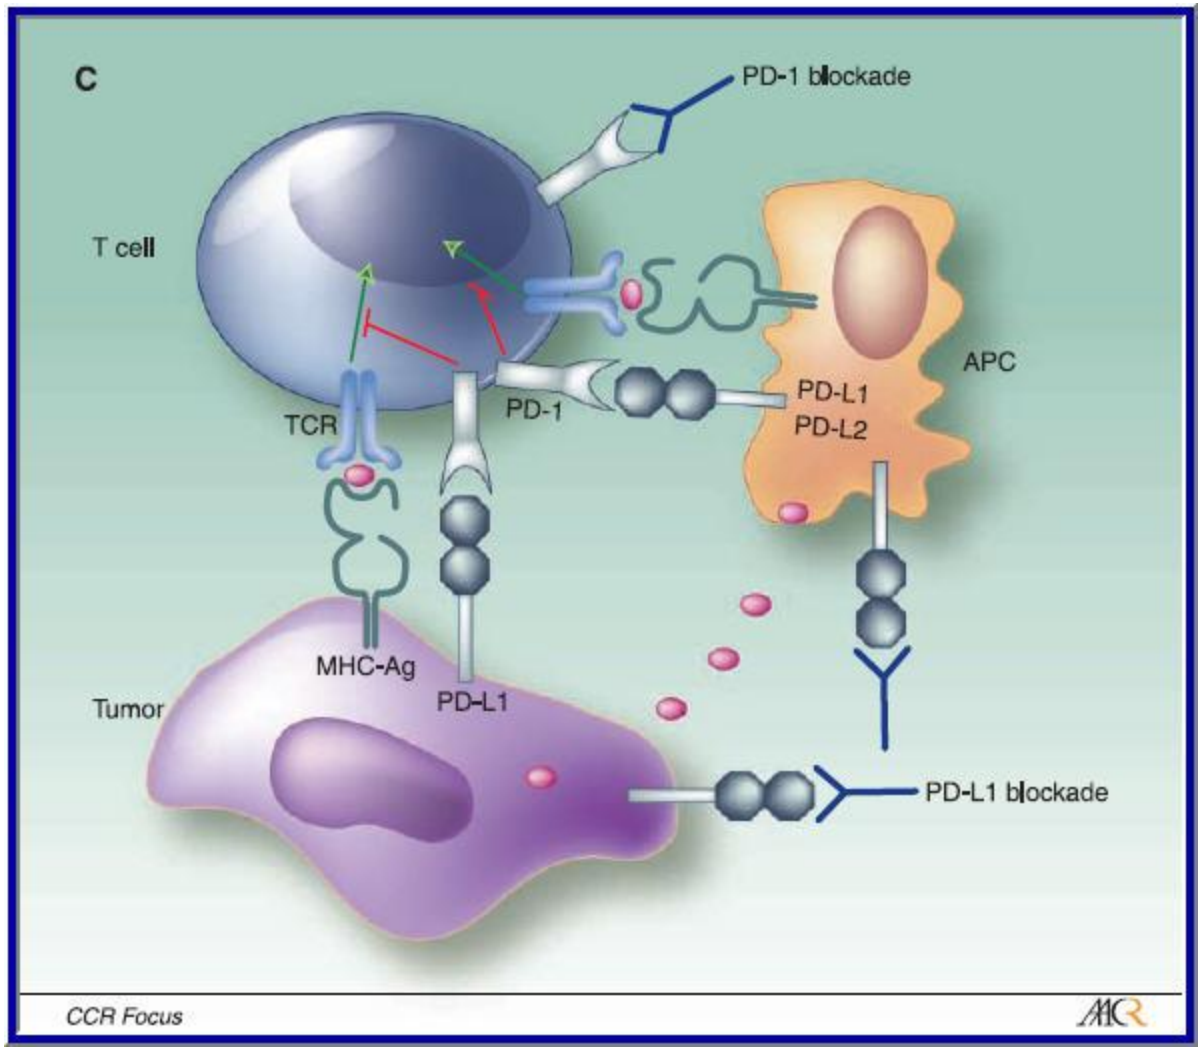
Kaplan-Meier Analysis of Survival



Survival Rate	Ipi + gp100 N=403	Ipi + pbo N=137	gp100 + pbo N=136
1 year	44%	46%	25%
2 year	22%	24%	14%

Hodi et al. NEJM 2010

Programmed Death 1



http://www.melanoma.org/community/mpip-melanoma-patients-information-page/video-how-anti-pd-1-therapy-works-imumne-system

Anti – PD-1 (BMS-936558)

296 Patients with Metastatic Cancer
1, 3, 10 mg/kg, MTD not reached

Safety: Adverse events similar to Ipilimumab, but 4% pneuomonitis (3 deaths)

Clinical Activity:

- **Melamona (n= 94): 28% CR/PR, 6% SD**
- **NSCLC (n=76): 18% CR/PR, 7% SD**
- **RCC (n= 33): 27% CR/PR, 27% SD**
- ***CRC (n=19), CRPC (n=13): No responses***

Immunotherapies: Dosing Challenges

Ramy Ibrahim, M.D.
MedImmune

Conventional dose/schedule selection and anti-cancer development

- Preclinical data from efficacy studies to identify target exposures in human
- Escalate doses in FTIH studies to assess safety and achieve target exposures (or higher) to increase likelihood of early signal
- Determine the MTD after DLTs are observed
- Select MTD for further development in randomized studies to assess efficay
- Initiate registrational studies

Novelties with immune-modulators and implications on dose/schedule selection

- Animal data might not inform dose selection
  - Cross reactivity and finding surrogate has limitations
- The “target” is the immune system and not the cancer
  - Complexity of the interaction between the immune system and cancer
  - Patients might have different threshold or sensitivity to immune priming
    - We need to identify a dose that achieves appropriate exposure while accommodating inter-patient variability
- Immune targets are dynamic
  - Variability in target level, site of expression, tumor type and tumor burden
- Animal data and PK modeling might only inform the starting dose and identify a target exposure range

Novelties with immune-modulators and implications on dose/schedule selection (cont)

- Dose escalation till “toxicity” is not a viable approach
    - None of the PD1/PDL1 targeting antibodies reached an MTD
    - Activity observed at multiple dose levels
    - Early phase clinical PK, target related biomarkers, markers of immune response and clinical activity should be leveraged
    - Need for novel phase I designs to inform dose selection

Novelties with immune-modulators and implications on dose/schedule selection (cont)

- Dose-ranging comparative studies may not necessarily better inform dose selection
  - Tremelimumab development
    - Randomized phase II suggested 15 mg/kg q3mo to be associated with more favorable risk: benefit
    - Phase III study suggested 15mg/kg Q 3 months not to maintain desired AUC
    - Currently exploring monthly dosing
- Beside dose/schedule, what about duration of treatment?
- Due to the early and sometimes dramatic signal of activity, programs progress quickly from large phase 1 to phase 3
  - How to design better studies to inform registrational studies

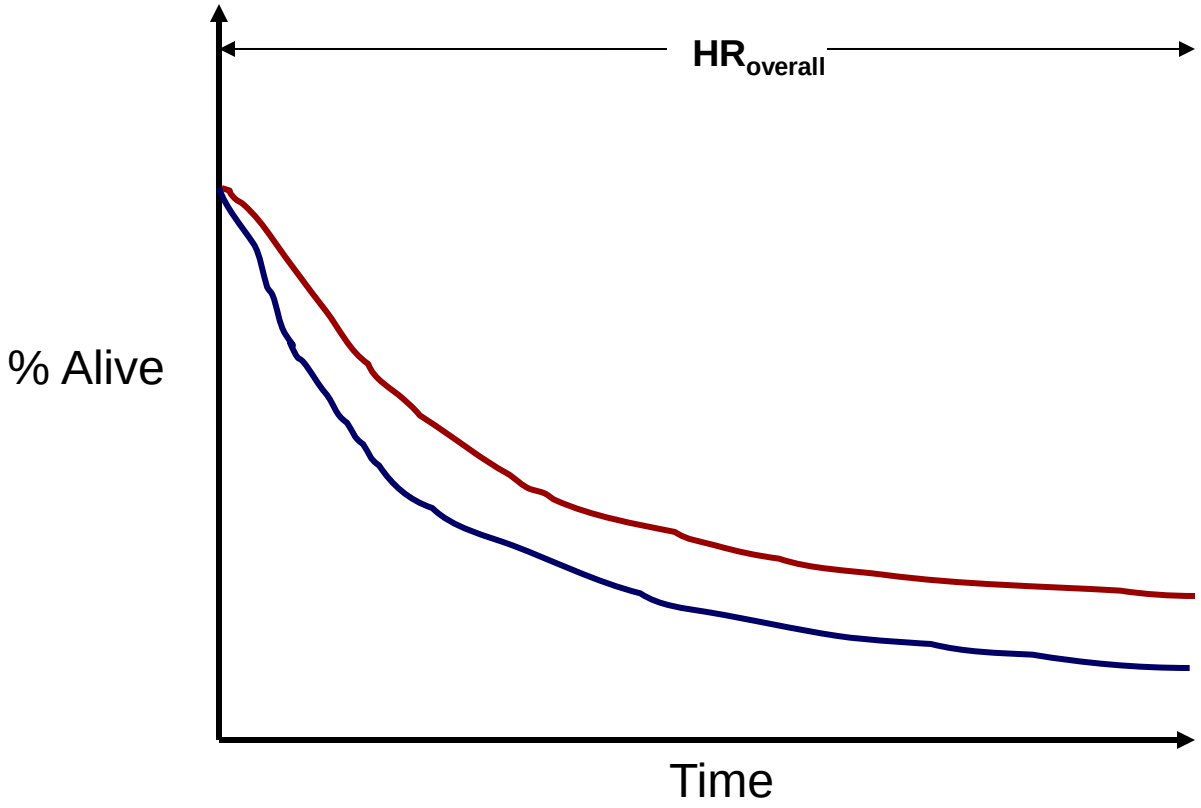
CIC Cancer Immunotherapy Consortium

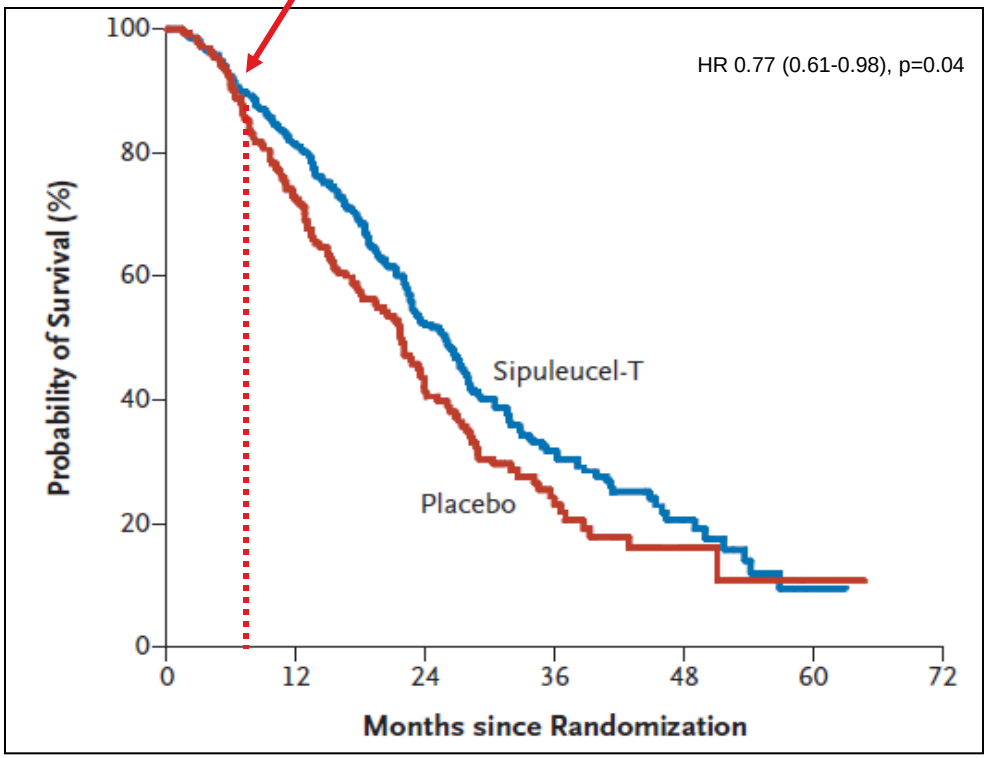
Survival: Conventional Design Assumptions



- No events occur before separation of curve
- Proportional hazard applies

Delayed Separation – Sipuleucel-T

Separation of curves
at ~8 months



Sponsor:
Dendreon

Agent:
autologous dendritic cell vaccine

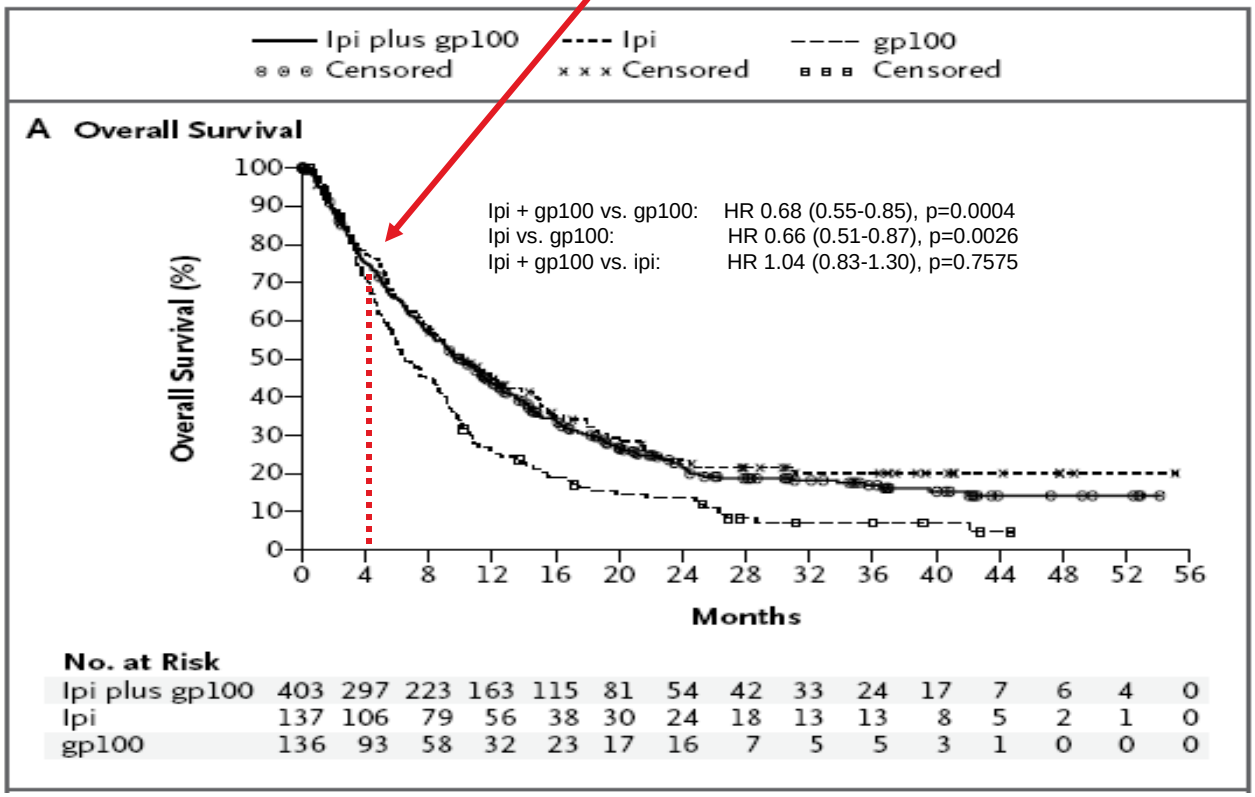
Disease:
hormone-refractory prostate cancer

Kantoff et al., New Engl. J. Med. 2010

Cancer Immunotherapy Consortium

Delayed Separation – Ipilimumab

Separation of curves
at ~4 months



Sponsor:
BMS

Agent:
Anti-CTLA-4 mAb

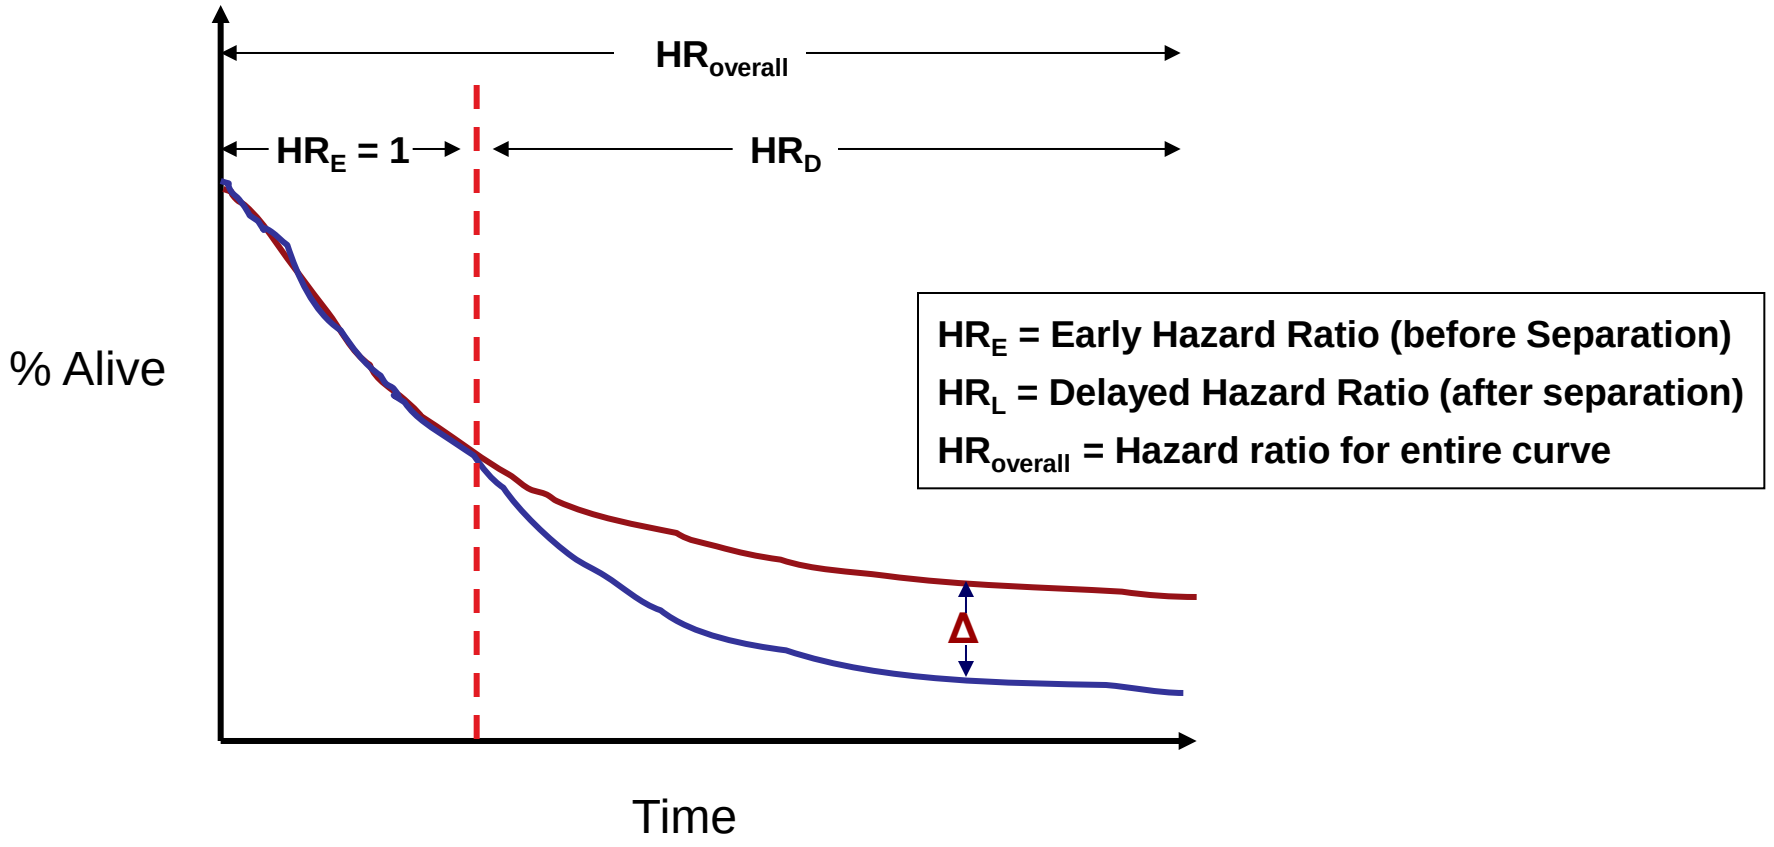
Disease:
Metastatic melanoma

Hodi et al., New Engl. J. Med. 2010

Cancer Immunotherapy Consortium

Implications of Delayed Separation of Curves

- Model Scenario -



- **Large Δ after separation needed to compensate for no effect before separation**

Intermediate Endpoints for Immune Checkpoint Modulators: Milestone OS Analysis

Tai-Tsang Chen, Ph.D.
Bristol-Myers Squibb

Rationale

- Unique characteristics of immune checkpoint modulators
  - Survival probability (long term survival)
  - Delayed clinical effect

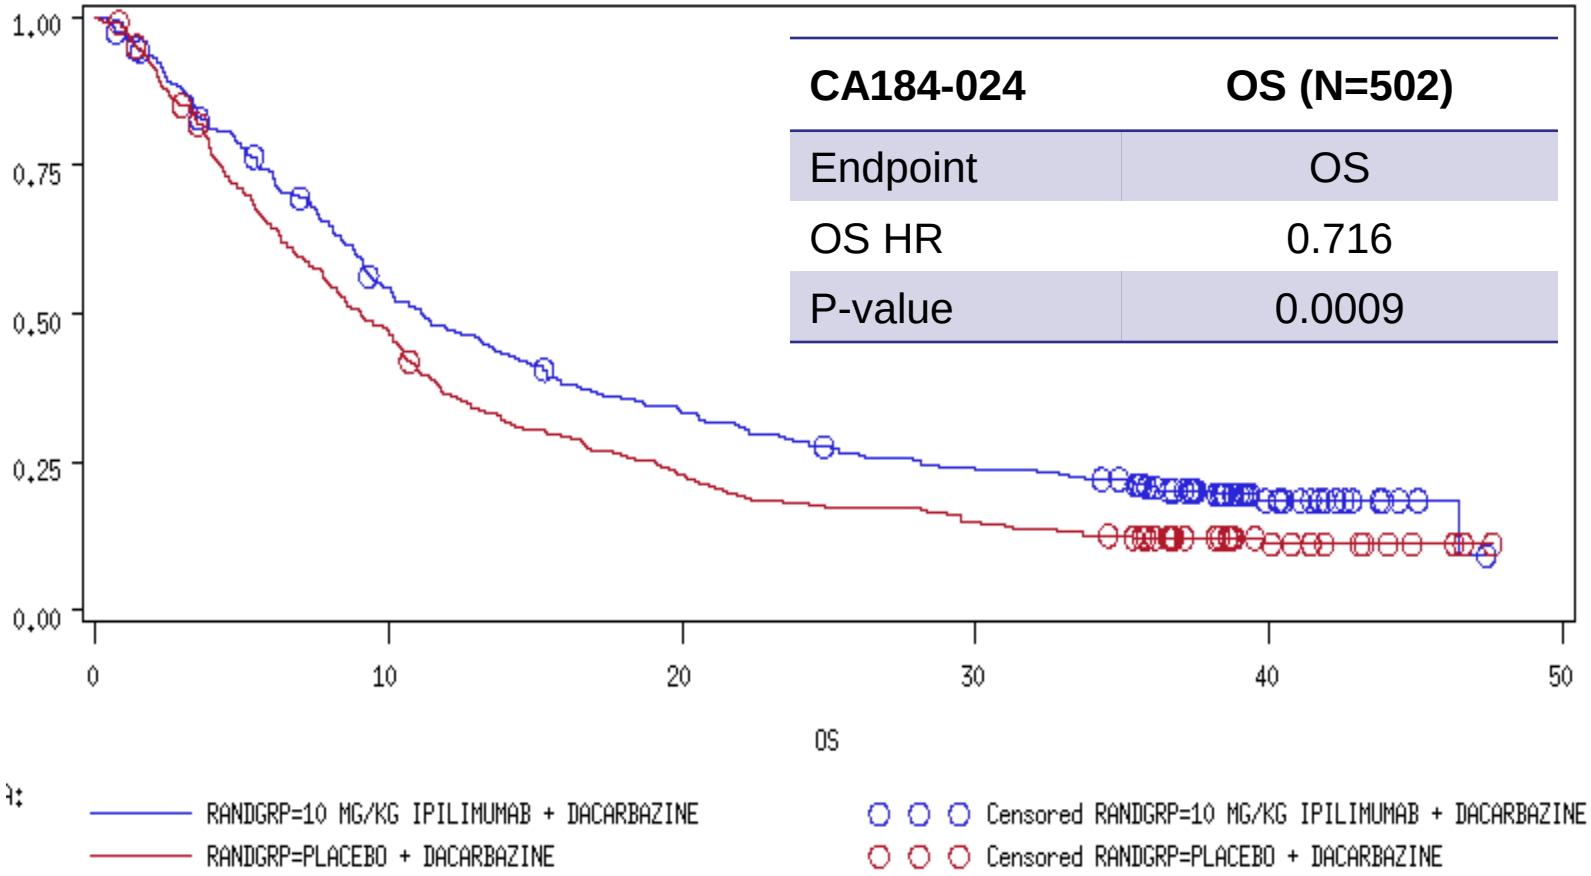
- Key challenges of log-rank analysis as sole characterization of overall survival
  - Does not capture key attribute of survival probability (or long term survival)
  - Time to final analysis may continue to lengthen based on kinetics of survival effect

Milestone OS Analysis

- Milestone survival is defined as the Kaplan-Meier survival probability at a pre-specified milestone, e.g., 2 years

- Study design and analysis consideration
  - Primary endpoint: overall survival
  - Intermediate endpoint: milestone survival probability
  - Population includes patients with a minimal follow-up duration, i.e., ≥ milestone duration
  - Hierarchical testing procedure

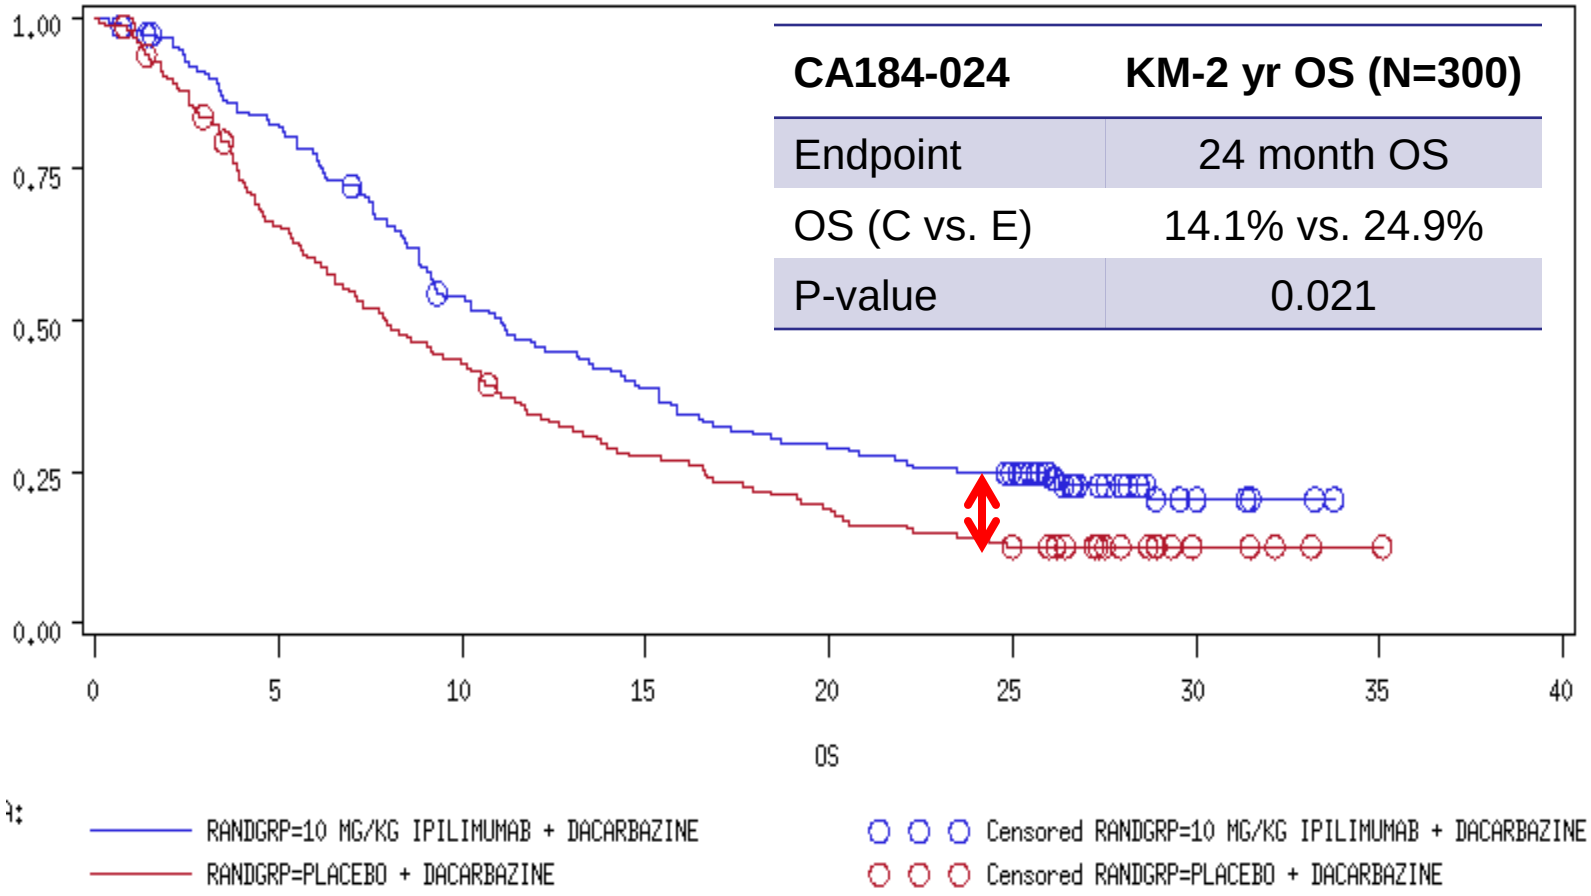
Example*: Ipilimumab+DTIC vs. DTIC Final OS Analysis



CA184-024	OS (N=502)
Endpoint	OS
OS HR	0.716
P-value	0.0009

* Roberts, C. et al. NEJM, 2011, 364: 2517-2526.

Example*: Ipilimumab+DTIC vs. DTIC Intermediate 2-year Milestone OS Analysis



CA184-024	KM-2 yr OS (N=300)
Endpoint	24 month OS
OS (C vs. E)	14.1% vs. 24.9%
P-value	0.021

* Roberts, C. et al. NEJM, 2011, 364: 2517-2526.

Pros and Cons

- Pros
  - Potential earlier assessment of benefit/risk
  - Greater statistical power when delayed treatment effect is present
  - Direct characterization of survival probability (long term survival effect)
  - Predictable timing of analysis
  - Both intermediate and final endpoints are overall survival
- Cons
  - Challenge in maintaining study integrity post milestone analysis, i.e., unblinding prior to final OS analysis
  - Does not account for the totality of OS data
  - Only appropriate for a registration trial when prior data enable an understanding of appropriate milestone time point selection
